The first part of the paper is devoted to a discussion of the
 various methods which have been proposed for the determination of
 the rate of reaction between a solid and a liquid. It is found that
 the most reliable method is that of measuring the change in weight
 of the solid as the reaction proceeds. This method is applicable to
 all cases in which the solid is insoluble in the liquid and the
 reaction is not too rapid. In cases where the reaction is too rapid
 for this method to be applicable, other methods have been proposed,
 such as the measurement of the volume of gas evolved, or the
 change in viscosity of the liquid. These methods are less reliable
 than the weight method, but they can be used in certain cases.
 The second part of the paper is devoted to a discussion of the
 factors which influence the rate of reaction between a solid and a
 liquid. It is found that the rate of reaction is influenced by the
 nature of the solid, the nature of the liquid, the temperature, and
 the surface area of the solid. The rate of reaction is generally
 increased by increasing the temperature, and by increasing the
 surface area of the solid. The rate of reaction is also influenced
 by the nature of the solid and the nature of the liquid.
